

Schmid-style fixation benchmark — b3_seed0 (N=20, 1% action + 1% observation error, $\beta=1$)

Payoff advantage of the candidate, per composition
 above 0 = candidate fitter at that mix; crossing 0 = interior equilibrium
 shaded band = ± 1 s.d. over 5 replicates
 (!) 1 probe(s) still drifting (worst ALLD at 0.10); raise --burn-in

Fixation probability vs the neutral benchmark
 whiskers = rho at ± 1 s.d. of the 5-replicate payoff spread
